AUTOMATIC ORDERING METHOD AND SYSTEM FOR TRADING OF STOCK, BOND, ITEM, FUTURE INDEX, OPTION, INDEX, CURRENT AND SO ON

BackGrouNP
~~BACKGROUDN~~ OF THE INVENTION

FIELD OF THE INVENTION

5   The present invention relates to an automatic ordering method and system for trading of stocks, bonds, items, futures, options, indexes, foreign currencies through data communication network, and more particularly to an automatic ordering method and system by way of computer according to a predetermined condition set by an investor.

10   Known are the method and system for trading articles such as stocks, foreign exchanges, cereals, ores, futures and the like. In the conventional method and system, an investor inputs into a computer desired purchase (or selling) price and desired purchase (or selling) quantity of certain articles, securities, foreign exchanges or indexes to generate a trade order and to
15   conclude a trade. In this regard, trade method of articles, foreign currency exchanges, securities, indexes and the like through a computer network is the same as the current stock trade method through a computer network, such that the present invention will be described hereinafter with reference to a stock trade by way of example.

20   With reference to the stock trade as an example, the present invention relates to a method and a system, where a user pre-set a trade condition for purchase or selling order for a particular stock, and a computer places an automatic purchase or selling order according to the trade condition.

           It has been a general practice for a stock holder to directly order a
25   selling or buying of a stock at a securities company or to commission an employee at a securities company to order a selling or buying of a stock under

his or her own decision. When a stock holder intends to order a selling or buying of stock, he or she visits a securities company in person, calls the company, uses a radio communication terminal provided by the company, utilizes a personal computer communication network system or uses an

5 internet.

Now, recent stock trade method at a stock exchange market (SEM) and some of the terminologies in relation to stock trade are briefly described using the example of Korea Stock Exchange (KSE).

As of February 1999, a stock price is based on a closing of a previous

10 day and can rise or fall within a range of 15% thereof. The KSE opens at 9 in the morning during workdays except for holidays, weekend and yearend, and closes at 3 in the afternoon. A "daily upper limit" in the stock dealing means a price 15% soared above the closing price of the previous day and a "daily lower limit" defines a price 15% declined based on the closing price of the

15 previous day.

Purchase and sale of a stock are made from 9 a.m. when the stock market opens to 3 p.m., but orders for stock dealing can be reserved even from 5 p.m. to before 9 a.m. the following day after the market is closed in case a communication by computer, ARS, Internet and the like are utilized.

20 Referring to Figure 1, a buying and selling method of stocks after order thereto is given utilizing the communication by computer or Internet is described hereinafter.

A stock holder uses his or her computer system 10 to connect same to a computer system 2 of a securities company the stock holder deals with, and

25 to confirm a balance of an account, residual quantity of stocks, present price or closing price of his or her present stock. Then when the stock holder orders

2

a buying or a selling of a particular stock, the order is recorded in the computer system of the securities company, which is then transferred to a computer system 30 of the KSE after a usual procedure necessary for the sale and purchase of the stock dealings is processed in the securities company.

When the order of sale and purchase is received via a network 40 from the securities company, the computer system 30 in the KSE compares selling order price and quantity and buying order price and quantity and allows a purchase and sale to be concluded at a particular price.

Generally, this kind of buying and selling is repeated from opening to closing of the stock market. This kind of method is similarly performed when the stock holder visits the securities company. Only difference is that a step is deleted where a stock holder utilizes his or her computer system 10 to input a particular data.

In order to contract this kind of deals, whether the deal is a purchase order or a sale order, an item code of a stock to be bought or sold, desired purchasing or selling price, desired purchasing or selling quantity and the like should be input via a computer or ARS by a stock holder or a staff at the securities company.

Under the stock dealing method thus described, a predetermined fundamental information data (by way of example, stock account, secret number, etc) and buying/selling condition information data (by way of example, stock item code, desired buying/selling prices, desired buying/selling quantity, etc) should be input via the computer system 10 or 20 by a stock holder or staff at the securities company at every dealing time point. Furthermore, in order to place a buying or selling order corresponding to a particular purchase or sale, buying or selling contract details at every moment should be monitored and an order corresponding thereto should be

3

However, there is a problem in these types of behaviors in that lots of time are consumed and people who are busy at offices and who can hardly spend time at securities company cannot cope therewith.

5 There is another problem in that staff at the securities company spend too much time in placing every buying or selling order, in the view point of the securities company, too much personal expenses are spent, and if there is any erroneous input of necessary information data due to erroneous typing and the like, the securities company is compelled to sustain a large amount of
10 economic loss.

Meanwhile, many stock investors are thinking about provisional desired purchase price, purchase quantity, desired selling price and selling quantity of particular stock in which they intend to invest. However, in order to comprehend whether the current price of the stock has reached a desired
15 purchase or selling price, they should be always aware of the stock price change at the stock market. However, it is not that easy to constantly observe the changing stock prices.

SUMMARY OF THE INVENTION

The present invention is disclosed to solve the aforementioned
20 problems and it is an object of the present invention to provide an automatic ordering method and system for allowing an investor to invest without concerning himself or herself about stock market change and new information.

The present invention also provide an automatic ordering method and system adapted to repeatedly place purchase and selling orders according to
25 predetermined conditions on behalf of investors including individual investors and institutional investors.

In accordance with one object of the present invention there is provided an automatic ordering method, the automatic ordering method for trading of stocks, bonds, items, futures, options, indexes, foreign currencies and the like through data communication network comprises the steps of:

5   determining a trade-desired object and inputting an automatic trade condition containing purchase and selling conditions in a computer system;

issuing purchase and/or selling order(s) according to the automatic trade conditions through the data communication network;

discriminating whether the purchase order and/or selling order has

10   been contracted through the data communication network; and

placing new purchase and/or selling order(s) by the computer through the data communication network according to the automatic trade conditions when either the purchase order or the selling order is contracted.

In accordance with another object of the present invention, there is

15   provided an automatic stock ordering method using a computer system connected to a data communication network, the method comprising the steps of:

determining a trade-desired stock and inputting an automatic trade condition including purchase and selling conditions at the computer system;

20   placing through the data communication network a stock purchase order or stock selling order according to the trade condition;

discriminating whether or not the stock selling order or stock purchase order has been contracted through the data communication network; and

placing by a commuter through the data communication network a

25   new stock selling or purchase order according to the automatic trade condition when the stock selling or purchase order is contracted.

In accordance with still another object of the present invention, there is provided an automatic stock ordering method, the method of trading stocks using a computer system connected to data communication network, the

method comprising the steps of:

determining a trade-desired stock and inputting an automatic trade condition including a purchase condition and a selling condition in the computer system;

5 placing through the data communication network one or more than one stock selling order(s) and one or more than one stock purchase order(s) according to the trade condition;

discriminating whether or not the stock selling or purchase order has been contracted through the data communication network; and

10 placing by the computer through the data communication network new stock selling and purchase orders according to the automatic stock trade condition when the stock selling or purchase order is contracted.

In accordance with still further object of the present invention, there is provided an automatic ordering system of stocks, the stock ordering system 15 including a user computer system connectable to a computer system at the Korea Stock Exchange through a data communication network, the system comprising:

a user interface at the user computer system;

a memory device for storing a basic information data including item 20 code of stock and account number of a stock holder input to the computer system through the user interface;

a trade condition control module for storing automatic stock trade condition data containing desired selling price, desired selling quantity, desired purchase price, desired purchase quantity for trade of the stock input 25 to the computer system through the user interface; and

a trade order control module for discriminating whether the automatic stock trade condition has been met and for placing a stock trade order

according to the automatic stock trade condition through the data communication network if the condition is met.

BRIEF DESCRIPTION OF THE DRAWINGS

For fuller understanding of the nature and objects of the invention, reference should be made to the following detailed description taken in conjunction with the accompanying drawings in which:

Figure 1 is a conceptual drawing of a stock dealing system via a network;

Figure 2 is a conceptual block diagram for illustrating an embodiment of an automatic ordering system of stock dealings according to the present invention;

Figure 3 is a flow chart for illustrating the first and the second embodiments of an automatic ordering method of stock dealings according to the present invention;

Figure 4 is a user interface for illustrating the first and the second embodiments of an automatic ordering method of stock dealings according to the present invention;

Figure 5 is a flow chart for illustrating the third and the fourth embodiments of an automatic ordering method and system of stock dealings according to the present invention;

Figure 6 is a user interface for illustrating the third and the fourth embodiments of an automatic ordering method and system of stock dealings according to the present invention; and

Figure 7 is an automatic trade table generated by the third and the fourth embodiments according to the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Preferred embodiments of the present invention will now be described

7

in detail with reference to the accompanying drawings.

Figure 2 is a conceptual block diagram for illustrating a first embodiment of an automatic ordering system of stock dealings or stock trade according to the present invention.

5   In other words, an automatic ordering system of stock dealing according to the present invention (hereinafter referred to an "automatic ordering system") can be embodied, as illustrated in Figure 1, by user computer system 10 (hereinafter referred to as "user 's computer"), a computer system of securities company 20 and a computer system of SEM 10   30 mutually connected for performing data communication via a network 40.

Furthermore, the user computer 10, where an automatic ordering system according to the present invention can be embodied, includes a user interface 12 for interfacing with a stock holder, a trade (deal) condition control module 16 for storing information on a stock holder (by way of example, 15   name, quantity, and purchasing price of possessed stock, and available balance and automatic trade conditions established by the stock holder and for revising to a new stock dealing condition according to user manipulation or concluded deal state, and a trade order control module 14 for issuing a dealing order of concerned stock according to the automatic trade conditions.

20   Of course, the user computer 10, although not illustrated in Figure 2, further includes softwares such as operation system necessary for operation of the computer system and various applications and hardwares such as central processing unit and hard disks. The user computer still further includes hardwares (not shown) such as a modem, a LAN adapter for 25   executing a data communication with the computer system 20 at a securities company or with the computer system 30 at the SEM and softwares such as data communication control application and the like, and all these are

8

~~generally called as a communication control module (not shown).~~

[handwritten] The computer system 20 at the securities company, connected to the user computer 10 via the network 40 in order to perform a data communication, includes an administrator's interface 22 for interfacing with an administrator of the securities company, a deal (trade) performing module 24 for receiving an order from the user computer 10 and transmitting same to the computer system 30 at SEM to thereby allow a stock dealing to be concluded, and an account control module 26 for storing a useable balance and stock residual quantity of stock account of a particular stock holder and for amending same according to contracted dealings.

It should be also noted that the computer system 20 at the securities company is further disposed with hardwares and softwares for executing a general function as a computer system, quite similar to those of the user computer 10.

Part or whole of modules 14 and 16 of the user computer 10 may be integrated to a computer system 20 of a securities company. Construction may be made such that a user is simply connected to a company of a securities company through the user interface 12. Furthermore, in a country where it is legally allowed for a user to directly connect to a computer system 30 of a stock market in placing a stock trade order, the computer system 20 of a securities company may be integrated to the user computer 10.

[handwritten] In case a securities company invests in a stock on behalf of a client, hardward and software resources of the user computer 10 are integrated to the computer system 20 of the securities company.

Next, the computer system 30 at the SEM is provided with an administrator interface 32 for interfacing an administrator of the SEM, a deal

9

(trade) conclusion control module 34 for receiving and comparing a purchase order and a selling order from each computer system 20 at every securities company to thereafter conclude the dealings and a stock price control module 36 for correcting the stock price according to the concluded stock quantity and price. The computer system 30 at the SEM further includes softwares and hardwares for performing a general function as a computer system, quite similar to those of the user computer 10 or computer system 20 at the securities company.

Each module illustrated in Figure 2 performs a mutual data communication within a computer system each module belongs to, and a data communication is executed via the data communication control module even among the modules included in other computer systems. Data flow and connecting relation according to performance of these data communication are schematically illustrated by two-way arrows in Figure 2. Although Figure 2 illustrates a block diagram where the user computer 10 is directly connected to the computer system 30 of the SEM, it should be noted that the direct connection is not indispensable but the user computer 10 may be connected only to the computer system 20 of the securities company. Hardwares and softwares for accomplishing the data communication are well known to a person who has ordinary knowledge in a technical field to which the present invention belongs (hereinafter referred to as "a person skilled in the art"), and detailed description of the hardwares and softwares will not be made here as they are not directly necessary matters in describing subject matters of the present invention.

It is an easy matter for a person in the art to adequately arrange or change computer system resources between the user computer 10, computer system 20 of a securities company and computer system 30 of KSE. Accordingly, it should be noted that Figure 2 is just shown for illustrating one embodiment and a system for embodying the present invention may be

variably modified by a person in the art.

Next, embodiments of the automatic stock ordering method and system will be described in detail with reference to Figures 3, 4, 5, 6 and 7.

Figure 3 is a flow chart for illustrating a first embodiment of automatic ordering method according to the present invention.

According to the first embodiment, when the automatic ordering system starts operation, step 300, a basic data including a stock account number, a secret number thereof, name and registration number of stock holder, item code of possessed stock and the like are registered through the user interface 12 of the user computer 10 and are stored. A one-time registration of the basic information data suffices at the initial start of the automatic ordering system and there is no need of additional registration unless the basic information data is to be amended.

Next, the stock holder establishes an automatic trade condition for selling and purchasing certain items of stocks, step 302. A user interface as shown in Figure 4 may be provided to the user to expedite the establishment of the automatic trade condition.

A item code selection button 401 in Figure 4 is selectively provided to search or select a share to invest in. In order to select a stock of ABC company 403 as investment item, an item code of the ABC company 403, by way of example, '00660' 402 may be selected or input. A referral button 404 of share price of previous day may be selectively provided. An amount to be used for automatic trade is entered in an amount entry column 405. The entry amount should not necessarily accord with remainder in the stock account. When there remains possessed stocks to be automatically traded, the number of stocks to be automatically traded are entered in a column 406. The number

11

of stocks entered into the column 406 should not be necessarily the whole possessed stocks.

Establishment of initial trade condition is not part of the present invention. The initial trade condition is the same as the method and system
5 provided for cyber stock investors by the current securities companies. A referral button 407 of current share price is a selective item.

Column 408 is a button for selecting purchase or selling. The present example has established an initial trade where 100 shares 410 of ABC company are purchased 408 at 25,000 Korean Won per share.

10 The automatic trade condition is based on a presumption that an initial trade will be contracted. In order to set up an automatic trade condition, columns 412 and 422 for selecting selling or purchase, columns 414, 418, 424 and 428 for selecting unit price and quantity at fixed quantity or fixed rate, and columns 416, 420, 426 and 430 for entering the unit price or
15 quantity at fixed quantity or fixed rate are provided.

The present example as a first automatic trade condition has established a selling 412 of 100 shares 420 purchased at the initial trade at 27,000Won per share.

A second automatic trade condition based on the contract of the first
20 condition is established at purchase 422 more increased in quantity 428 and 430 by 200% and lower unit prices 424 and 426 by 20% than those of the first trade. In other words, the condition is buying 200 stocks at 21,600Won per share.

These kinds of automatic trade conditions may be established up to
25 an appropriate number, by way of example, up to a fifth condition or up to a tenth condition, in the same method. The automatic trade condition is

12

confirmed by pressing a confirmation button 432. However, the automatic trade condition is allowed to be changed or amended at all times by a user.

A selling order according to the predetermined first condition is generated by computer regardless of the current share price right after the
5   initial trade is contracted. In other words, a discrimination is made at step 306 in Figure 3 as to whether the automatic trade condition is a purchase or a selling, and if the condition is established as selling as illustrated in Figure 4, flow advances to step 310 to discriminate whether the selling condition has been met. The discrimination of the selling condition is a discrimination as to
10   whether established selling quantity of share is possessed, or whether a designated selling price is within an allowable trade range (i.e., daily upper limit and daily lower limit).

If the condition is met, a selling order is automatically generated by computer, step 316, and the computer discriminates whether the selling order
15   is contracted, step 318.

If the selling order is not contracted on the same day, same order is generated by computer every day until the selling order is concluded. If the order is contracted, the account remainder and share residual quantity are amended, step 320, and the computer discriminates whether or not the
20   condition is met according to the previously set-up second automatic trade condition. If the second condition is met, a new order is immediately generated. In other words, as soon as the first a trade is concluded, a second trade order is actually created. A stock trade order is automatically generated by the computer as much as the automatic trade condition is established
25   according to this method. When the established automatic trade conditions are all concluded, automatic trade is stopped. In the present invention, completion of the automatic trade is advised to a user by an appropriate method. This method may include beeper, E-mail, cellular telephone or the like.

13

This notifying method can be realized by well-know technologies.

The first embodiment includes a step 304 for receiving the closing price of previous day and a step 312 for notifying an error when the purchase or selling condition is not met at steps 308 and 310.

5　　　　A discrimination should be made as to whether established trade price is within the daily upper limit or daily lower limit when the stock trade order is placed only within the limits as in Korea, and if the order is placed out of the limits, errors 312 are created. Furthermore, in case only partial quantity of trade order is concluded, or trade is fulfilled at a price different from trade

10　　order price (Handling of this case will be described later), an instance can occur where account remainder and stock residual quantity remain against anticipation to thereby generate an error.

If an error happens, the automatic trade is stopped and generation of error is advised to a user by an appropriate method. When the error is notified,

15　　the user may change or amend the automatic trade condition to thereafter process the automatic trade continuously.

According to the first embodiment, it is possible for the user to perform the trade of shares as desired without continuously monitoring changes of the stock market.

20　　　　Step 304 in Figure 3 at the second embodiment of the present invention includes a step for receiving the closing price of the previous day and the present price of concerned stock as well for comparison with the automatic trade condition. There is a disadvantage in the first embodiment in that, when a stock trade order is created regardless of the current price or

25　　invested money is too much, an investment strategy may be exposed to other investors. The second embodiment therefore makes the stock purchase order

14

or selling order generated when the present price at the stock market reaches an established price of established automatic trade condition, or makes the stock selling order created when the present price is lower by a predetermined percentage (by way of example, 5%) than established automatic selling price,

5 or makes the stock purchase order created when the current price is higher by a predetermined percentage (by way of example, 4%) than established automatic purchase price.

The second embodiment can be embodied by additionally providing at the automatic trade condition establishment column of Figure 4 an

10 establishment column for limiting a generated period of time of the trade order, and by comparing the current price with trade order generation time condition established at steps 308 and 310 in Figure 3. Under these circumstances, if the time condition is not met, steps 308 and 310 should be continuously checked until the time condition is satisfied without creating an

15 error 312. The time condition comparison means according to the second embodiment may be utilized by a known art to integrate a trade order control module 14 and a trade condition control module 16 in Figure 2.

Now, a third embodiment of the present invention will be described with reference to Figures 5, 6 and 7. At though the first and second

20 embodiments is characterized in that either the purchase order or selling order is automatically created according to established automatic trade condition, the third embodiment of the present invention is characterized in that both the purchase order and selling order are simultaneously generated according to the established automatic trade conditions as described later.

25 As illustrated in Figure 5, a system is activated, step 500, according to the third embodiment to set up an automatic trade condition, step 502.

The automatic trade condition may be established by providing an

15

interface to a user as exemplified in Figure 6. Remaining portions except the automatic trade condition set-up unit in Figure 6 are the same as those indicated in reference numerals 401 through 410 in Figure 4.

However, in the present embodiment, an example is given as 5 possessing 10,000 shares of DEF company and selling 100 shares of DEF company at 10,000Won per share.

A standard quantity 602 in the automatic trade condition establishes a standard selling and purchase at every automatic trade. Fee rates (and tax) of securities company to be paid at the share trading are entered into a column 10 604, which is not essential but conducive to calculation of profits after the stock trading. Purchase price and selling quantity of automatic trade are established at columns 606, 608, 610 and 612. The purchase price may be established at a predetermined lower price or at a predetermined lower rate than the selling price at every trading.

15 An automatic purchase price lower by 500Won than the selling price is established at every trading in Figure 6.

Furthermore, automatic purchase quantity may be established at a fixed rate or at a fixed quantity in column 610. If the column 612 is blank, the automatic purchase order at every trading is 100 shares as the set-up 20 standard quantity 602. Plus(+) and minus(-) symbols may be used in column 612, and in case of using plus(+), the automatic purchase order quantity is increased by a fixed rate or fixed quantity, and in case of using minus(-), the automatic purchase order quantity is decreased by a fixed rate or by fixed quantity.

25 The automatic selling condition is also set up in columns 614, 616, 618 and 620 in the same manner as above. The present embodiment is

established as automatically selling 100 shares at a price more increased or more decreased by 1,000Won than the initial selling price at every trading. An extra trade condition may be established at a fixed rate or at a fixed quantity in columns 622 and 624. The extra trade condition will be further described

5   later.

The user may establish a target profit or earning rate at column 626. If the target profit rate is not set-up, the automatic trading continues unless stopped by the user. However, it is easy for the computer to calculate an earning rate at every automatic trading, and it is preferable to automatically

10   stop the automatic trading when a certain profit rate is earned.

The user may use a trade table application button 628 to draw up an automatic trade table as shown in Figure 7. However, the automatic trade table can be imaginary, so that make-up of visual table is selective. In other words, the system according to the present invention can realize the third

15   embodiment of the present invention just by storing a formula or logic for drawing up the automatic trade table 700.

The automatic trade table 700 in Figure 7 is made according to the automatic trade establishment condition in Figure 6.

The automatic trade table 700 is made such that each selling price in

20   selling row 714 is less by 1,000Won at each line thereof while each purchase price at each purchase row 712 is less by 500Won than each corresponding line of selling price.

On the automatic trade table 700, prices in the same lines as in 702 through 710 are appropriately adjusted up and down on the basis of the initial

25   trade price.

Unlike the example in Figure 6, in case the trade condition is

17

determined at a fixed rate of percentage, purchase price or selling price of the trade table or order quantity may be created in decimal points. However, the KSE has stipulated that shares should be traded on a 50Won unit base in case a share price is ranged between 10,000Won to 50,000Won, to thereby limit units of trade price and quantity, and if the stipulation cannot be observed, share price is changed to an approximate one or rounded to amend the trade table.

In most of cases, the trade table is adjusted to an approximate price to cater to trade regulations of each country, which can be automatically performed by computer, each column in the trade table is allowed to be amended in order quantity, selling price or purchase price as a user desires. Figure 7 is an example not amended or changed. The trade table 700 is confirmed by a trade table confirmation button 716 pressed by a user.

With reference to Figure 5, as soon as an initial selling succeeds, a first automatic purchase order and automatic selling order are created by the automatic trade table according to the automatic trade condition previously set up, step 512. In the third embodiment, it is designed "to buy the same stock at a lower price and to sell at a higher price". Accordingly, when an initial selling order is concluded, a purchase order at a price just below the contracted initial selling price (10,000Won) (i.e. purchase of 100 shares at a purchase price of 9,500Won) is placed (see line 706 in Figure 7), and a selling order at a price just higher than the contracted selling price (i.e. selling of 100 shares at a selling price of 11,000Won) is placed (see selling column at line 704 in Figure 7).

These selling and purchase orders are within the account balance and possessed number of shares, such that no errors are generated at steps 506 and 508.

When a purchase order is contacted as ordered in a first automatic trade order, a purchase order and a selling order approximate to the order price contracted in the automatic trade table 700 are generated. As previously mentioned the third embodiment is so designed as to buy "at a lower price" than just-contracted price "and sell at a higher price", such that a second automatic trade order is created through steps of Figure 5 (steps 514, 516, 506 and 508) where a purchase order (100 shares purchased at 8,500Won, see line 708 in Figure 7) and a selling order (100 shares sold at 10,000Won) are placed.

When a selling order is concluded at the second automatic trade order, a purchase order (100 shares bought at 9,500Won) close to contracted order price (10,000Won at the second order) and a selling order (100 shares sold at 11,000Won) are automatically generated at the third automatic order. In order words, each automatic trade order generates a purchase order at a price just lower than the contracted price at the automatic trade table 700 and a selling order just higher than the contracted price.

When an automatic trade is performed according to the third embodiment, a certain profit is created in case the share price vertically fluctuate around a price range of the initial trade price. By way of example, in case a share price in Figure 7 rises from 10,000Won to 14,000Won and drops to 10,000Won, a predetermined earning is generated. Furthermore, even in case a share price drops from 10,000Won to 4,000Won and rises to 10,000Won, a certain profit is gained. As apparent from this, the third embodiment may be an appropriate investment method for a stock where a share price thereof frequently and vertically fluctuates at a certain price range.

The extra trade condition in Figure 6 may be established to increase a selling quantity and purchase quantity in case an automatic trade is again generated at the same price after the automatic trade is initiated, in other

words, in case a purchase order and selling order are twice generated at the same price according to fluctuation of the share price.

Referring to Figure 5 again, a discrimination is made as to whether a purchase condition and a selling condition are met by comparing the established automatic trade condition with balance of securities account and possessed stocks, steps 506 and 508. In order to buy stocks, at least more money should remain in the account than established purchase quantity multiplied by established purchase price, and in order to sell, at least more stocks are possessed than the desired selling quantity. In case only purchase is continuously contracted by the automatic trade, possessed balance in the securities account may be drained out, and in case only selling is continuously concluded, a case may occur where possessed stocks are drained out.

In case steps 506 and 508 are met, the automatic trade purchase order and selling order are simultaneously generated, step 512, and in case the steps 506 and 508 are not satisfied, an error occurs, and the occurrence of error is notified to the stock investor by an appropriate method, step 510.

By way of example, the occurrence of error may be so established that an error message is displayed on the user interface or an alarm sound may be generated. Furthermore, a system may be so constructed as to notify to the stock investor by way of wire, wireless or pager when an error happens. These kinds of error notifying methods may be realized by known arts.

As mentioned above, in case steps 506 and 508 are satisfied, stock purchase order and stock selling order are created, step 512. At this time, it should be noted that the purchase order and selling order are generated at the same time.

The third embodiment is quite different in this regard from the

20

conventional stock investment method. In the third embodiment, the current share price is disregarded and price change of stocks is not anticipated at all.

According to the third embodiment, a certain quantity is purchased when a share price drops compared with previously bought share price and when the share price rises compared with the previously purchase share price, a certain quantity is sold.

A discrimination is made as to whether or not a trade is contracted at step 514. The contracted trade order may be either a selling order or a purchase order, or neither order can be contracted. In case both orders are not contracted, same purchase order and selling order are created on the next day. Exceptional cases such as partial contract, a contract with a price different from an order price and the like may occur. In case of partial contract, whole order quantity may be considered as contracted, or a selling order and purchase order of the same price for the stocks not contracted may be generated.

Furthermore, in case a contract is made at a price different from the order price, a purchase order just below a contracted price and a selling order just above the contracted price are created.

Whichever order is concluded, account balance and stock remainders are revised, step 516, and if condition is met according to the automatic trade condition pre-set up at steps 506 and 508, a new purchase order and a new selling order are immediately generated.

In the third embodiment, a closing price is received from the computer system 20 or the KSE computer system 30, step 504 to use same as a discriminating reference of purchase condition and selling condition. In case ex-dividend or the like occurs, cases may occur where reference price is

21

different from the closing price of previous day. Furthermore, many exceptional circumstances such as reduction of capital, stock split, consolidation in par value and the like can happen in the stock market and when these cases happen, it is necessary to automatically stop the automatic
5   trade by way of system.

A fourth embodiment of the present invention is a variation of the third embodiment and is characterized in that at least two or more than two purchase orders and at least two or more than two selling orders are simultaneously created. In case there occur a large volume of purchase orders
10   or selling orders in the stock market, trade orders in various price ranges are concurrently concluded to rapidly and broadly change the stock prices.

In case three selling orders and three purchase orders are set up to be simultaneously generated in the fourth embodiment, three selling orders, each above 10,000Won based on initial contract price of 10,000Won, (i.e., 100
15   shares sold, each at 11,000Won, 100 shares sold, each at 12,000Won and 100 shares sold, each at 13,000Won) and three purchase orders, each below 10,000Won of initial contract price (i.e., 100 shares bought, each at 9,500Won, 100 shares bought, each at 8,500Won and 100 shares bought, each at 7,500Won) are concurrently created, as in Figure 7.

20   If any one of the six orders is contracted, balance of five orders is immediately cancelled the moment above one contract is concluded, and as automatic trade orders thereafter, one purchase order and one selling order corresponding to the contract in the third embodiment are created. The fourth embodiment is particularly useful to reserve orders before the stock market is
25   open and after the stock market is closed. The fourth embodiment may be embodied by additionally providing a column for limiting the number of plural orders in the automatic trade condition of Figure 6.

The first, second, third and fourth embodiments according to the present invention are embodied by the system illustrated in Figures 1 and 2. Information received from the computer system 30 of KSE or other computer (not shown) connected to Internet is compared with automatic trade condition

5   priorly set up by a user according to the trade condition control module 16 to discriminate whether or not purchase condition and/or selling condition are/is satisfied. As a result of the discrimination, if the condition(s) is(are) met, a selling order and/or purchase order are(is) placed with the trade performing module 24 of the computer system 20 at the securities company according to

10 the trade order control module 14.

This kind of discrimination and trade order is repeatedly executed, with receipt of a market information on real time from the activated start of automatic order system such that the trade orders are placed several times in a day. Once the trade order is placed by the trade order control module 14,

15 the account control module 26 discriminates whether account balance and remaining stocks are not out of limit, and the trade order is, once placed, transmitted to the computer system 30 of KSE by the trade performing module 24.

The trade conclusion control module 34 at the computer system of

20 KSE receives the order to compare same with trade order of other securities companies, and if an appropriate price is formed, the trade is accomplished where the trade contract is notified to the trade performing module 24. The trade performing module 24 again notifies the contracted price and quantity to the account control module 26 and the trade condition control module 14,

25 against which the account control module 26 rectifies the balance and remaining quantity, where the trade condition control module 14 separately stores the actually contracted trade condition and amends the trade condition according to the user instruction or set-up state.

Although the present invention has been described with reference to specific embodiments, the invention is not intended to be limited to the embodiments disclosed, which are considered to be purely exemplary. Although the above embodiment has described a desired purchase price,

5 selling price and trade quantity as automatic trade condition of stocks, other conditions such as increase/decrease of composite share index, increase/decrease of stock trade volume, technical index and the like may be established as automatic trade condition.

Furthermore, although the present invention has described about

10 stocks, bonds, future, options, foreign current exchanges, grains, minerals, index swaps and the like which are traded in the similar manner as stocks may be applied.

As apparent from the foregoing, there is an advantage in the automatic ordering method and system for trading of stocks according to the present

15 invention thus described in that an investor can reduce loss of time consumed for monitoring stock market situation or for input of orders, while securities company can decrease time and cost for inputting and managing the trade orders.

There is another advantage in that a possibility of erroneously

20 inputting data necessary for stock trade orders can be fundamentally ruled out to thereby prevent investment loss resulted from the erroneous input.
